## Parameterized Curves and Surfaces (in $\mathbb{R}^n$ )

### 1.1 Parameterized Curves

**Definition** A parameterized curve is a continuous function

$$f : I \rightarrow \mathbb{R}^n$$

where  $I$  is an open set in  $\mathbb{R}$ .

#### 1.1.1 Examples

1. Straight line:  $f : \mathbb{R} \rightarrow \mathbb{R}^2$  defined as  $f(\alpha) = (\alpha, m\alpha + c)$  where  $m$  and  $c$  are constants.
2. Parabola:  $f : \mathbb{R} \rightarrow \mathbb{R}^2$  defined as  $f(\alpha) = (\alpha, m\alpha^2)$  where  $m$  is a constant.
3. Circle:  $f : \mathbb{R} \rightarrow \mathbb{R}^2$  defined as  $f(\alpha) = (\cos \alpha, \sin \alpha)$ .

- Function is bounded.
- There is no polynomial parameterization of this curve.
- Rational Parameterizations exists:

$$f(t) = \left( \frac{t^2 - 1}{t + 1}, \frac{2t}{t + 1} \right)$$

4. Not involving Modulus:  $f : \mathbb{R} \rightarrow \mathbb{R}^2$  defined as  $f(\alpha) = (\alpha^3, \alpha^2)$ .

#### 1.1.2 Differentiation Curves:

A function  $f$  which is differentiable for all  $t \in I$  is called a Parameterized Differentiable Curves [for all possible parameterizations]. Let  $f(t) = (f_1(t), f_2(t), \dots, f_n(t))$ , then its derivative is defined as:  $f'(t) = (f'_1(t), f'_2(t), \dots, f'_n(t))$ . This is used to define the direction of the tangent at a point  $f(t)$  as  $f'(t)$ .

**Regular Curve:** A differentiable curve such that the tangent vector is non-zero for all  $t \in I$

## 1.2 Paramterized Surfaces
